

Q1) The bias-variance tradeoff describes the issue in many machine learning problems between minimizing bias and variance, which inherently affect each other.

The bias problem is when in a classification machine learning problem the hypothesis space made available does not include sufficient hypotheses. That is, a high bias would give a large error when a particular classification model is underfitting. On the other hand, the variance problem is when in a classification machine learning problem, the hypothesis space made available is too large for the training data and the selected hypothesis may not be accurate on new data. That is, a high variance may lead to overfit data. As evident by definition, the bias-variance tradeoff is the conflict between complex and simple classification algorithms, and it is impossible to have no bias and no variance, but instead an algorithm should have to be in the middle ground. One example of how to lower bias and variance is by including a penalty term to loss function, which will discourage the model from assigning too much importance to any one specific feature. To reduce bias specifically, we can increase the model complexity to reduce underfitting. To reduce variance, we can use techniques like resampling, such as in a random forest.

Here, the bias can stay the same, as we average many trees.

Other ensemble methods like bagging, boosting, and stacking can help in reducing the variance and bias.

$$2) \text{ Precision: } \frac{TP}{(TP+FP)}$$

$$\text{Recall: } r = \frac{TP}{TP+FN}$$

$$F_1: \frac{2TP}{p+r}$$

$$\text{Class 1: } TP = 50$$

$$FP = 40$$

$$FN = 30$$

$$\text{Class 2: } TP = 60$$

$$FP = 30$$

$$FN = 40$$

$$\text{Precision: Class 1} = \frac{50}{90} = 0.5556$$

$$\text{Class 2} = \frac{60}{90} = 0.6667$$

$$\text{Recall: Class 1: } \frac{50}{80} = 0.625$$

$$\text{Class 2: } \frac{60}{100} = 0.6$$

$$F_1 = \text{Class 1: } \frac{2 \cdot \frac{5}{9} \cdot \frac{5}{8}}{\frac{5}{9} + \frac{5}{8}} = 0.5884$$

$$F_2 = \text{Class 2: } \frac{2 \cdot \frac{6}{9} \cdot \frac{6}{10}}{\frac{6}{9} + \frac{6}{10}} = 0.6316$$

# 3) Entropy(6,4)

\* Using base 10

$$= \frac{4}{10} \log \frac{4}{10} - \frac{6}{10} \log \frac{6}{10} = 0.2922852532$$
